```

where \underline{depvar} is the dependent variable, indvar is the independent variable for binning, and covars are other covariates to be controlled for.

p, s and v are integers satisfying 0 <= s,v <= p, which can take different values in each case

fweights and pweights are allowed; see weight.

Description

binsqreg implements binscatter quantile regression with robust inference procedures and plots, following the results in Cattaneo, Crump, Farrell and Feng (2021a). Binscatter provides a flexible way of describing the quantile relationship between two variables, after possibly adjusting for other covariates, based on partitioning/binning of the independent variable of interest. The main purpose of this command is to generate binned scatter plots with curve estimation with robust pointwise confidence intervals and uniform confidence band. If the binning scheme is not set by the user, the companion command binscatter in a data-driven (optimal) way. Hypothesis testing about the regression function can be conducted via the companion command binscatter in a data-driven comparison can be conducted via the companion command binspwc. Binscatter estimation based on the least squares method can be conducted via the command binspwc. Binscatter estimation based on the least squares method can be conducted via the command binspwc.

A detailed introduction to this command is given in $\underline{\text{Cattaneo, Crump, Farrell and }}$ $\underline{\text{Feng (2021b)}}$. A companion R package with the same capabilities is available (see website below).

Companion commands: <u>binstest</u> for hypothesis testing, and <u>binsregselect</u> data-driven (optimal) binning selection.

Related Stata and R packages are available in the following website:

https://nppackages.github.io/

Options

Estimand

- quantile (#) specifies the quantile to be estimated and should be a number between 0 and 1, exclusive. The default value of 0.5 corresponds to the median.
- $\operatorname{deriv}(v)$ specifies the derivative order of the regression function for estimation, testing and plotting. The default is deriv(0), which corresponds to the function itself.
- at (position) specifies the values of covars at which the estimated function is evaluated for plotting. The default is **at(mean)**, which corresponds to the mean of covars. Other options are: at(median) for the median of covars, at(0) for zeros, and at (filename) for particular values of covars saved in another file.
- Note: when at(mean) or at(median) is specified, all factor variables in covars (if specified) are excluded from the evaluation.

J _{Dots}

- $\mathtt{dots}(p\ s)$ sets a piecewise polynomial of degree p with s smoothness constraints for point estimation and plotting as "dots". The default is $\mathtt{dots}(0\ 0)$, which corresponds to piecewise constant (canonical binscatter).
- dotsgrid(dotsgridoption) specifies the number and location of dots within each bin to be plotted. Two options are available: mean and a numeric non-negative integer. The option dotsgrid (mean) adds the sample average of indvar within each bin to the grid of evaluation points. The option dotsgrid(#) adds # number of evenly-spaced points to the grid of evaluation points for each bin. Both options can be used simultaneously: for example, dotsgrid(mean 5) generates six evaluation points within each bin containing the sample mean of indvar within each bin and five evenly-spaced points. Given this choice, the dots are point estimates evaluated over the selected grid within each bin. The default is **dotsgrid**(mean), which corresponds to one dot per bin evaluated at the sample average of indvar within each bin (canonical binscatter).
- dotsplotopt (dotsoption) standard graphs options to be passed on to the twoway command to modify the appearance of the plotted dots.

____line

- $line(p \ s)$ sets a piecewise polynomial of degree p with s smoothness constraints for plotting as a "line". By default, the line is not included in the plot unless explicitly specified. Recommended specification is line(3 3), which adds a cubic B-spline estimate of the regression function of interest to the binned scatter plot.
- linegrid(#) specifies the number of evaluation points of an evenly-spaced grid within each bin used for evaluation of the point estimate set by the line(p s) option. The default is linegrid(20), which corresponds to 20 evenly-spaced evaluation points within each bin for fitting/plotting the line.
- lineplotopt(lineoption) standard graphs options to be passed on to the twoway command to modify the appearance of the plotted line.

Confidence Intervals

 $\operatorname{\mathtt{ci}}(p\ s)$ specifies the piecewise polynomial of degree p with s smoothness constraints used for constructing confidence intervals. By default, the confidence intervals are not included in the plot unless explicitly specified. Recommended specification is ci(3 3), which adds confidence intervals based on a cubic B-spline estimate of the regression function of interest to the binned scatter plot.

- cigrid(cigridoption) specifies the number and location of evaluation points in the grid used to construct the confidence intervals set by the $ci(p \ s)$ option. Two options are available: mean and a numeric non-negative integer. option **cigrid**(mean) adds the sample average of indvar within each bin to the grid of evaluation points. The option **cigrid**(#) adds # number of evenly-spaced points to the grid of evaluation points for each bin. Both options can be used simultaneously: for example, cigrid (mean 5) generates six evaluation points within each bin containing the sample mean of *indvar* within each bin and five evenly-spaced points. The default is **cigrid(***mean***)**, which corresponds to one evaluation point set at the sample average of indvar within each bin for confidence interval construction.
- $\begin{array}{c} \textbf{ciplotopt(}\textit{rcapoption)} & \textbf{standard graphs options to be passed on to the } \\ \textbf{twoway} \\ \textbf{command to modify the appearance of the confidence intervals.} \end{array}$

☐ Confidence Band L

- $\operatorname{\mathbf{cb}}(p\ s)$ specifies the piecewise polynomial of degree p with s smoothness constraints used for constructing the confidence band. By default, the confidence band is not included in the plot unless explicitly specified. Recommended specification is cb(3 3), which adds a confidence band based on a cubic B-spline estimate of the regression function of interest to the binned scatter plot.
- cbgrid(#) specifies the number of evaluation points of an evenly-spaced grid within each bin used for evaluation of the point estimate set by the cb(p s) option. The default is $\mathbf{cbgrid}(20)$, which corresponds to 20 evenly-spaced evaluation points within each bin for confidence band construction.
- cbplotopt (rareaoption) standard graphs options to be passed on to the twoway command to modify the appearance of the confidence band.

 $^{flue{}}$ Global Polynomial Regression $^{flue{}}$

- polyreg(p) sets the degree p of a global polynomial regression model for plotting. By default, this fit is not included in the plot unless explicitly specified. Recommended specification is polyreg(3), which adds a fourth order global polynomial fit of the regression function of interest to the binned scatter plot.
- polyreggrid(#) specifies the number of evaluation points of an evenly-spaced grid within each bin used for evaluation of the point estimate set by the polyreg(p) option. The default is polyreggrid(20), which corresponds to 20 evenly-spaced evaluation points within each bin for confidence interval construction.
- polyregcigrid(#) specifies the number of evaluation points of an evenly-spaced grid within each bin used for constructing confidence intervals based on polynomial regression set by the polyreg(p) option. The default is polyregcigrid(0), which corresponds to not plotting confidence intervals for the global polynomial regression approximation.
- polyregplotopt (lineoption) standard graphs options to be passed on to the twoway command to modify the appearance of the global polynomial regression fit.

☐ Subgroup Analysis L

- by(varname) specifies the variable containing the group indicator to perform subgroup analysis; both numeric and string variables are supported. When by (varname) is specified, binsreg implements estimation and inference by each subgroup separately, but produces a common binned scatter plot. By default, the binning structure is selected for each subgroup separately, but see the option samebinsby below for imposing a common binning structure across subgroups.
- bycolors (colorstylelist) specifies an ordered list of colors for plotting each subgroup series defined by the option by().

- bysymbols (symbolstylelist) specifies an ordered list of symbols for plotting each subgroup series defined by the option by().
- bylpatterns (linepatternstylelist) specifies an ordered list of line patterns for plotting each subgroup series defined by the option by().

Partitioning/Binning Selection

- nbins(#) sets the number of bins for partitioning/binning of indvar. If not specified, the number of bins is selected via the companion command binsregselect in a data-driven, optimal way whenever possible.
- binspos(position) specifies the position of binning knots. The default is binspos(qs), which corresponds to quantile-spaced binning (canonical binscatter). Other options are: es for evenly-spaced binning, or a numlist for manual specification of the positions of inner knots (which must be within the range of indvar).
- binsmethod(method) specifies the method for data-driven selection of the number of bins via the companion command binsregselect. The default is binsmethod(dpi), which corresponds to the IMSE-optimal direct plug-in rule. The other option is: rot for rule of thumb implementation.
- nbinsrot(#) specifies an initial number of bins value used to construct the DPI number of bins selector. If not specified, the data-driven ROT selector is used instead.
- samebinsby forces a common partitioning/binning structure across all subgroups specified by the option **by()**. The knots positions are selected according to the option **binspos()** and using the full sample. If **nbins()** is not specified, then the number of bins is selected via the companion command binsregselect and using the full sample.
- randcut(#) specifies the upper bound on a uniformly distributed variable used to draw a subsample for bins selection. Observations for which runiform() <= # are used. # must be between 0 and 1.

」 Simulation └

- nsims(#) specifies the number of random draws for constructing confidence bands and hypothesis testing. The default is nsims(500), which corresponds to 500 draws from a standard Gaussian random vector of size [(p+1)*J - (J-1)*s].
- simsqrid(#) specifies the number of evaluation points of an evenly-spaced grid within each bin used for evaluation of the supremum (or infimum) operation needed to construct confidence bands and hypothesis testing procedures. The default is **simsgrid(20)**, which corresponds to 20 evenly-spaced evaluation points within each bin for approximating the supremum (or infimum) operator.
- simsseed(#) sets the seed for simulations.

☐ Mass Points and Degrees of Freedom

dfcheck(n1 n2) sets cutoff values for minimum effective sample size checks, which take into account the number of unique values of indvar (i.e., adjusting for the number of mass points), number of clusters, and degrees of freedom of the different statistical models considered. The default is dfcheck(20 30). See Cattaneo, Crump, Farrell and Feng (2021b) for more details.

masspoints(masspointsoption) specifies how mass points in indvar are handled. By
 default, all mass point and degrees of freedom checks are implemented.
 Available options:

 ${\tt masspoints} \ (noadjust)$ omits mass point checks and the corresponding effective sample size adjustments.

masspoints(nolocalcheck) omits within-bin mass point and degrees of freedom
checks.

masspoints(off) sets masspoints(noadjust) and masspoints(nolocalcheck)
simultaneously.

masspoints (veryfew) forces the command to proceed as if indvar has only a few number of mass points (i.e., distinct values). In other words, forces the command to proceed as if the mass point and degrees of freedom checks were failed.

☐ Standard Error

asyvar(on/off) specifies the method used to compute standard errors. If
asyvar(on) is specified, the standard error of the nonparametric component is
used and the uncertainty related to other control variables covars is omitted.
Default is asyvar(off), that is, the uncertainty related to covars is taken
into account.

Other Options

level(#) sets the nominal confidence level for confidence interval and confidence
band estimation.

usegtools(on/off) forces the use of several commands in the community-distributed
 Stata package gtools to speed the computation up, if on is specified. Default
 is usegtools(off).

For more information about the package **gtools**, please see https://gtools.readthedocs.io/en/latest/index.html.

noplot omits binscatter plotting.

savedata(filename) specifies a filename for saving all data underlying the binscatter plot (and more).

replace overwrites the existing file when saving the graph data.

 ${\tt plotxrange}\,({\it min max})$ specifies the range of the x-axis for plotting. Observations outside the range are dropped in the plot.

plotyrange(min max) specifies the range of the y-axis for plotting. Observations outside the range are dropped in the plot.

twoway options any unrecognized options are appended to the end of the twoway command generating the binned scatter plot.

Examples

Setup

. sysuse auto

Run a binscatter median regression and report the plot

. binsqreg price weight length foreign, quantile(0.5)

Add confidence intervals and confidence band

. binsqreg price weight length foreign, quantile(0.5) ci(3 3) cb(3 3)
