```

where <u>depvar</u> is the dependent variable, <u>indvar</u> is the independent variable for binning, and <u>othercovs</u> are other covariates to be controlled for.

p, s and v are integers satisfying 0 <= s,v <= p, which can take different values in each case.

fweights and pweights are allowed; see weight.

Description

binsqreg implements binscatter quantile regression with robust inference
 procedures and plots, following the results in <u>Cattaneo, Crump, Farrell and Feng (2021a)</u>. Binscatter provides a flexible way to describe the quantile relationship between two variables, after possibly adjusting for other covariates, based on partitioning/binning of the independent variable of interest. The main purpose of this command is to generate binned scatter plots with curve estimation with robust pointwise confidence intervals and uniform confidence band. If the binning scheme is not set by the user, the companion command <u>binsregselect</u> is used to implement binscatter in a data-driven way. Hypothesis testing for parametric specifications of and shape restrictions on the regression function can be conducted via the companion command <u>binstest</u>. Hypothesis testing for pairwise group comparisons can be conducted via the companion command <u>binstest</u>. Binscatter estimation based on the least squares method can be conducted via the command <u>binsreg</u>.

A detailed introduction to this command is given in Cattaneo, Crump, Farrell and <a href="Feng (2021b). A companion R package with the same capabilities is available (see website below).

Companion commands: <u>binstest</u> for hypothesis testing for parametric specifications and shape restrictions, <u>binspwc</u> for hypothesis testing for pairwise group comparisons, and <u>binsregselect</u> data-driven binning selection.

Related Stata and R packages are available in the following website:

https://nppackages.github.io/

Options

____ Estimand

- quantile(#) specifies the quantile to be estimated and should be a number between 0 and 1, exclusive. The default value of 0.5 corresponds to the median.
- $\operatorname{deriv}(v)$ specifies the derivative order of the regression function for estimation, testing and plotting. The default is deriv(0), which corresponds to the function itself.
- at (position) specifies the values of othercovs at which the estimated function is evaluated for plotting. The default is **at(mean)**, which corresponds to the mean of *othercovs*. Other options are: **at(median)** for the median of *othercovs*, at(0) for zeros, and at(filename) for particular values of othercovs saved in another file.
- Note: when at (mean) or at (median) is specified, all factor variables in othercovs (if specified) are excluded from the evaluation (set as zero).

」 _{Dots}

- $\mathtt{dots}(p\ s)$ sets a piecewise polynomial of degree p with s smoothness constraints for point estimation and plotting as "dots". The default is $\mathtt{dots}(0\ 0)$, which corresponds to piecewise constant (canonical binscatter).
- dotsgrid(dotsgridoption) specifies the number and location of dots within each bin to be plotted. Two options are available: mean and a numeric non-negative integer. The option dotsgrid (mean) adds the sample average of indvar within each bin to the grid of evaluation points. The option dotsgrid(#) adds # number of evenly-spaced points to the grid of evaluation points for each bin. Both options can be used simultaneously: for example, dotsgrid(mean 5) generates six evaluation points within each bin containing the sample mean of indvar within each bin and five evenly-spaced points. Given this choice, the dots are point estimates evaluated over the selected grid within each bin. The default is **dotsgrid**(mean), which corresponds to one dot per bin evaluated at the sample average of indvar within each bin (canonical binscatter).
- dotsplotopt (dotsoption) standard graphs options to be passed on to the twoway command to modify the appearance of the plotted dots.

____line

- $\mbox{line($p$ s)}\mbox{ sets a piecewise polynomial of degree p with s smoothness constraints}$ for plotting as a "line". By default, the line is not included in the plot unless explicitly specified. Recommended specification is line(3 3), which adds a cubic B-spline estimate of the regression function of interest to the binned scatter plot.
- linegrid(#) specifies the number of evaluation points of an evenly-spaced grid within each bin used for evaluation of the point estimate set by the line(p s) option. The default is linegrid(20), which corresponds to 20 evenly-spaced evaluation points within each bin for fitting/plotting the line.
- lineplotopt(lineoption) standard graphs options to be passed on to the twoway command to modify the appearance of the plotted line.

Confidence Intervals

 $\operatorname{\mathtt{ci}}(p\ s)$ specifies the piecewise polynomial of degree p with s smoothness constraints used for constructing confidence intervals. By default, the confidence intervals are not included in the plot unless explicitly specified. Recommended specification is ci(3 3), which adds confidence intervals based on a cubic B-spline estimate of the regression function of interest to the binned scatter plot.

- cigrid(cigridoption) specifies the number and location of evaluation points in the
 grid used to construct the confidence intervals set by the ci(p s) option.
 Two options are available: mean and a numeric non-negative integer. The
 option cigrid(mean) adds the sample average of indvar within each bin to the
 grid of evaluation points. The option cigrid(#) adds # number of
 evenly-spaced points to the grid of evaluation points for each bin. Both
 options can be used simultaneously: for example, cigrid(mean 5) generates six
 evaluation points within each bin containing the sample mean of indvar within
 each bin and five evenly-spaced points. The default is cigrid(mean), which
 corresponds to one evaluation point set at the sample average of indvar within
 each bin for confidence interval construction.
- $\begin{array}{c} \textbf{ciplotopt(}\textit{rcapoption)} & \textbf{standard graphs options to be passed on to the } \\ \textbf{twoway} \\ \textbf{command to modify the appearance of the confidence intervals.} \end{array}$

Confidence Band

- cb(p s) specifies the piecewise polynomial of degree p with s smoothness
 constraints used for constructing the confidence band. By default, the
 confidence band is not included in the plot unless explicitly specified.
 Recommended specification is cb(3 3), which adds a confidence band based on a
 cubic B-spline estimate of the regression function of interest to the binned
 scatter plot.
- cbgrid(#) specifies the number of evaluation points of an evenly-spaced grid
 within each bin used for evaluation of the point estimate set by the cb(p s)
 option. The default is cbgrid(20), which corresponds to 20 evenly-spaced
 evaluation points within each bin for confidence band construction.
- cbplotopt(rareaoption) standard graphs options to be passed on to the twoway
 command to modify the appearance of the confidence band.

Global Polynomial Regression

- polyreg(p) sets the degree p of a global polynomial regression model for plotting.
 By default, this fit is not included in the plot unless explicitly specified.
 Recommended specification is polyreg(3), which adds a cubic polynomial fit of the regression function of interest to the binned scatter plot.
- polyreggrid(#) specifies the number of evaluation points of an evenly-spaced grid
 within each bin used for evaluation of the point estimate set by the
 polyreg(p) option. The default is polyreggrid(20), which corresponds to 20
 evenly-spaced evaluation points within each bin for confidence interval
 construction.
- polyregcigrid(#) specifies the number of evaluation points of an evenly-spaced
 grid within each bin used for constructing confidence intervals based on
 polynomial regression set by the polyreg(p) option. The default is
 polyregcigrid(0), which corresponds to not plotting confidence intervals for
 the global polynomial regression approximation.
- polyregplotopt(lineoption) standard graphs options to be passed on to the twoway
 command to modify the appearance of the global polynomial regression fit.

Subgroup Analysis

- by(varname) specifies the variable containing the group indicator to perform subgroup analysis; both numeric and string variables are supported. When by(varname) is specified, binsreg implements estimation and inference for each subgroup separately, but produces a common binned scatter plot. By default, the binning structure is selected for each subgroup separately, but see the option samebinsby below for imposing a common binning structure across subgroups.
- ${f bycolors}({\it colorstyle}list)$ specifies an ordered list of colors for plotting each subgroup series defined by the option ${f by}$ ().

- bysymbols (symbolstylelist) specifies an ordered list of symbols for plotting each subgroup series defined by the option by().
- bylpatterns (linepatternstylelist) specifies an ordered list of line patterns for plotting each subgroup series defined by the option by().

Partitioning/Binning Selection

- nbins(#) sets the number of bins for partitioning/binning of indvar. If not specified, the number of bins is selected via the companion command binsregselect in a data-driven, optimal way whenever possible.
- binspos(position) specifies the position of binning knots. The default is binspos(qs), which corresponds to quantile-spaced binning (canonical binscatter). Other options are: es for evenly-spaced binning, or a numlist for manual specification of the positions of inner knots (which must be within the range of indvar).
- binsmethod(method) specifies the method for data-driven selection of the number of bins via the companion command binsregselect. The default is binsmethod(dpi), which corresponds to the IMSE-optimal direct plug-in rule. The other option is: rot for rule of thumb implementation.
- nbinsrot(#) specifies an initial number of bins value used to construct the DPI number of bins selector. If not specified, the data-driven ROT selector is used instead.
- samebinsby forces a common partitioning/binning structure across all subgroups specified by the option **by()**. The knots positions are selected according to the option **binspos()** and using the full sample. If **nbins()** is not specified, then the number of bins is selected via the companion command binsregselect and using the full sample.
- randcut(#) specifies the upper bound on a uniformly distributed variable used to draw a subsample for bins selection. Observations for which runiform() <= # are used. # must be between 0 and 1.

」 Simulation └

- nsims(#) specifies the number of random draws for constructing confidence bands. The default is nsims(500), which corresponds to 500 draws from a standard Gaussian random vector of size [(p+1)*J - (J-1)*s].
- simsqrid(#) specifies the number of evaluation points of an evenly-spaced grid within each bin used for evaluation of the supremum operation needed to construct confidence bands. The default is $\mathbf{simsgrid}(20)$, which corresponds to 20 evenly-spaced evaluation points within each bin for approximating the supremum operator.
- simsseed(#) sets the seed for simulations.

Mass Points and Degrees of Freedom

dfcheck(n1 n2) sets cutoff values for minimum effective sample size checks, which take into account the number of unique values of indvar (i.e., adjusting for the number of mass points), number of clusters, and degrees of freedom of the different statistical models considered. The default is dfcheck(20 30). See Cattaneo, Crump, Farrell and Feng (2021b) for more details.

masspoints (masspointsoption) specifies how mass points in indvar are handled. By default, all mass point and degrees of freedom checks are implemented. Available options:

masspoints (noadjust) omits mass point checks and the corresponding effective sample size adjustments.

masspoints (nolocalcheck) omits within-bin mass point and degrees of freedom checks.

masspoints(off) sets masspoints(noadjust) and masspoints(nolocalcheck) simultaneously.

masspoints (veryfew) forces the command to proceed as if indvar has only a few number of mass points (i.e., distinct values). In other words, forces the command to proceed as if the mass point and degrees of freedom checks were failed.

☐ Standard Error

vce(vcetype) specifies the vcetype for variance estimation used by the command greg. Bootstrapping-based VCE can be also be obtained by setting vce (boot, reps(#)) where reps(#) specifies the number of bootstrap replications. Weights are not allowed when bootstrapping VCE is specified. The default is vce (robust).

asyvar(on/off) specifies the method used to compute standard errors. If asyvar(on) is specified, the standard error of the nonparametric component is
used and the uncertainty related to other control variables othercovs is omitted. Default is asyvar(off), that is, the uncertainty related to othercovs is taken into account.

→ Other Options L

level(#) sets the nominal confidence level for confidence interval and confidence band estimation.

usegtools(on/off) forces the use of several commands in the community-distributed Stata package gtools to speed the computation up, if on is specified. Default is usegtools(off).

For more information about the package gtools, please see https://gtools.readthedocs.io/en/latest/index.html.

noplot omits binscatter plotting.

savedata (filename) specifies a filename for saving all data underlying the binscatter plot (and more).

replace overwrites the existing file when saving the graph data.

plotxrange (min max) specifies the range of the x-axis for plotting. Observations outside the range are dropped in the plot.

plotyrange(min max) specifies the range of the y-axis for plotting. Observations outside the range are dropped in the plot.

twoway options any unrecognized options are appended to the end of the twoway command generating the binned scatter plot.

Examples

Setup

. sysuse auto

Run a binscatter median regression and report the plot

. binsqreg price weight length foreign, quantile(0.5)

Add confidence intervals and confidence band

. binsqreg price weight length foreign, quantile(0.5) ci(3 3) cb(3 3)
